Managing Energy Risks in the 21st Century

By Emmanuel Navon

Abstract:

The emergence of China as a major oil importer is feeding geopolitical tensions with the United States over the securing of oil supplies. The United States is also growingly concerned about the foreign policy goals that Russia promotes thanks to its energy resources. More than any other source of energy, oil is at the core of global geopolitical tensions because of its monopoly over transportation. Those tensions are likely to deteriorate with the expected depletion of oil resources. The solution to this intricate international problem lies in the undoing of oil's monopolistic status by promoting the use of biofuels and electricity in transportation.

About the Author:

Dr. Emmanuel Navon is the managing partner of the Navon-Levy Group Ltd., a consultancy that promotes and finances Israeli development projects in Africa in the fields of agriculture, renewable energies, and infrastructures. In addition, he teaches International Relations at Tel-Aviv University and serves on the boards of EMET, a Washington think-tank, and of the Center for International Communication at Bar-Ilan University. He is has been a fellow at the Shalem Center and at the Institute for Policy and Strategy at the IDC Herzliya. Emmanuel Navon graduated from Sciences-Po Paris and earned his Ph.D. in International Relations from the Hebrew University of Jerusalem.

Introduction

The global competition over energy resources creates geopolitical tensions between the world's major powers. Russia leverages its oil and gas resources to assert its regional power and global clout. China has become a major energy player in Africa and in the Middle-East, shielding countries such as Iran and Sudan from strong UN sanctions. The geopolitical rivalries over energy resources between the United States and China have reached such levels that US Senator Richard Lugar called for NATO to rephrase Article 5 of its Charter so as to define an energy embargo against a member state as an attack on the alliance. Although NATO has not (yet) endorsed this proposal, it did add energy security to its mission in 2006.

While the emergence of India and China has increased the demand for energy, oil and gas reserves are diminishing. The world's daily oil demand increased by 9.4 million barrels between 2000 and 2007, and nearly 85 % of that growth came from emerging markets.³ In recent years, oil and gas prices have risen to their highest level in history (from \$17 for a barrel of oil in January 1999 to \$147 in July 2008). The global energy demand will rise by 57% by 2030, and the combined energy demand of Asia will grow by 128% over that period.⁴ Moreover, the remaining known oil and gas reserves are concentrated in the Persian Gulf, in Central Asia and

in Russia. This means that oil and gas importing countries will be more and more dependent on undemocratic and politically unstable countries –unless they change their energy policies.

The oil crises of the 1970s prompted many countries to start developing nuclear and renewable energy sources as alternatives to fossil fuels. The discovery, in the 1980s, that fossil fuel combustion, by significantly increasing the amount of carbon dioxide in the atmosphere, contributes to the Earth's "global warming" encouraged further research and investment in nonfossil energies. Today, reducing fossil fuel consumption is not only a matter of environmental concern, but also of national security and of international stability. Most of the world's oil reserves are held by countries that are generally unstable, corrupt, authoritarian and hostile to the West. Hence, the surge of oil prices in the past decade has enabled countries such as Saudi Arabia, Iran, Russia and Venezuela to defy US foreign policy goals.

This paper argues that the most realistic and effective way of defusing geopolitical tensions over energy resources is to break the monopoly of oil over transportation. The paper's first section shows that the global competition over energy resources, especially oil, creates growing and potentially explosive geopolitical rivalries. The second section explains that the preponderance of oil in the global energy market has debilitating effects on the world economy and on international security, and that those negative effects are likely to worsen due to the depletion of oil reserves. The third section provides practical and realistic ways of reducing the world economy's dependence on oil. The article concludes that political will and international cooperation among oil-importing nations are critical to achieve energy security.

1. Energy and World Politics

Approximately 70% of conventional crude oil and about 65% of natural gas reserves are located in an area that spans from the Middle-East, via the Caspian region, to north-western Siberia. Europe's only source of oil production (in the North Sea) will be depleted by 2020 (the United Kingdom has once again become a net importer of petroleum products and of natural gas). Neither Russia nor the majority of the Gulf states are members of the World Trade Organization (WTO), which means that the mediation mechanism of the WTO would not be applicable to possible future conflicts between energy exporters and energy importers.

By the year 2030, the world's energy demand will be 57% higher than what it was in 2004. Since this demand will still be met, mostly, by nonrenewable fossil fuels (87%), the supply of oil, coal, and natural gas will have to be correspondingly much larger than what it is today. The production of oil will have to rise by 42%, the production of natural gas by 65%, and the production of coal by 74%. With many experts agreeing that worldwide oil production has reached a peak or is about to do so, a 42% increase is unrealistic.

In 2003, the Russian Government published an energy plan that openly admitted the policy goal of regaining control over energy distribution networks in neighboring countries. The document states that Russia must assert its global clout via oil and gas sales. Venezuela offers subsidized oil and gas shipments to its neighbors in order to influence their foreign policy. The fact that

Iran's foreign policy became openly confrontational vis-à-vis the United States in the mid-2000s is not unrelated to the rise of oil prices and revenues at the time.

Energy and world politics are closely intertwined. 75% of the world's proven oil reserves are controlled by government-owned companies. National oil companies increasingly form strategic alliances with one another to serve the foreign policy objectives of their state owners. Two-thirds of the world's oil trade is transported by tankers, many of which go through strategically and politically sensitive routes such as the Strait of Hormuz (in the Persian Gulf), the Strait of Malacca (between Indonesia and Malaysia), and the Bosporus Strait (in Turkey).

In June 2006, Iran threatened that it would respond to an attack on its nuclear installations with the blocking of the Strait of Hormuz, which it the most critical strait for oil and liquid gas transportation (about 20% of the world's energy supply is exported via Hormuz). As for the Strait of Malacca, half of the world's oil trade passes through it, including the Middle East's oil exports to China and Japan. The Strait of Malacca is a 2.4 km wide bottleneck and constitutes an ideal target for terrorist attacks. The Bosporus Strait is also a critical and sensitive route, especially for Russia's oil exports from its Black Sea ports.

Any major terrorist attack on energy infrastructures would have devastating effects. In February 2006, for example, a failed terrorist attack on Saudi Arabia's Abqaiq oil-processing tank caused a price increase of \$2.5 per oil barrel. Al Qaeda has threatened many times to attack energy infrastructures in Saudi Arabia.

1.1. Russia and the West

Russia is the world's largest energy exporter. It holds the world's largest reserves of natural gas, second largest reserves of coal, and seventh largest reserves of oil. Russia is also a major producer and exporter of nuclear energy. It borders China and the EU, two major energy importers. Because it has limited sea access, Russia relies on pipelines for its natural gas exports. Those pipelines go through transit states, many of which used to be satellites of the Soviet Union and are now NATO and/or EU members. As for Russia's oil exports, most of them go through Turkey's Bosporus Strait (itself a NATO member). On the one hand, Russia purchases energy infrastructures in neighboring countries, but on the other hand it does not allow foreign companies to buy energy infrastructures in Russia (which explains why Russia has not signed the EU's Energy Charter).

In January 2006, Russia's state monopoly Gazprom interrupted gas supplies to Ukraine. The official reason was that Ukraine refused to pay the sudden price increase imposed by Russia, but in reality Russia was blackmailing Ukraine into abandoning its bid to join NATO. US Vice-President Dick Cheney denounced Russia's use of gas and oil supplies as "tools of intimidation or blackmail." Gas supplies to Georgia were also interrupted, and the Georgian government accused Russia of sabotaging gas pipelines as a way of meddling in the dispute with the separatist republic of Southern Ossetia (in August 2008, Russia intervened militarily to secure Southern Ossetia's secession from the pro-Western Georgian Republic). As Argued by Daniel Freifeld, "If there were still any doubt about how far Russia would go to fight for its interests in

7

⁸ Russian President Dmitry Medvedev is the former chairman of Gazprom.

⁹ Speech in Vilnius, Lithuania, 4th May 2006 (http://www.nytimes.com/2006/05/04/world/europe/04cnd-cheney-text.html).

the Caucasus, Azerbaijan need only look at Georgia ... By attacking its small neighbor, Russia effectively warned not only Georgia but the whole neighborhood." Russia's strategy vis-à-vis Ukraine eventually "convinced" the latter to abandon the very idea of joining NATO: In April 2010, Ukraine's parliament ratified an agreement with Russia to keep the Russian Black Sea fleet in Sebastopol in exchange for the long-term delivery of cheaper Russian gas. ¹¹ This agreement removed any chance of Ukraine joining NATO.

The 1994 European Energy Charter forbids the deliberate interruption of energy transport, but Russia never ratified it. As argued by Sacha Müller-Kraenner, "The new great power politics of Russia focuses on the power of Gazprom, not on the weapons of the Red Army" and "Today, Russia has hardly any neighbor that it has not threatened with energy depravation as a weapon in the event of any political insubordination." Russia's use of energy to reassert its economic strength and international clout has undoubtedly paid off.

The main oil and gas pipelines that spread into Europe and Asia originate in Russia; they are controlled by the state monopolies Gazprom (for natural gas) and Transneft (for oil). ¹⁴ Europe purchases most of its natural gas from Russia, and is therefore trying to diversify its gas imports in order to reduce its dependency on Russia. ¹⁵ Meanwhile, European countries tend to act separately in order to guarantee their own secure gas deliveries from Russia. Hence is former German Chancellor Gerhard Schröder the chairman of the consortium in charge of building the Baltic Sea pipeline (the "Nord Stream Pipeline") between Russia and Germany. The fact that a former German Chancellor is on the Kremlin's energy payroll is highly symbolic and disturbing to many, given the fact that Russia supplies about a third of the EU's gas and that Europe's gas consumption is expected to be 40% higher by 2030.

Although Mr. Schröder claims that the Nord Stream pipeline will make Europe safer, a study by Sweden's Defense Research Agency argues that it will actually divide the EU and increase dependence on Russia. Poland's Foreign Minister went as far as to compare the North European Pipeline to the Molotov-Ribbentrop Pact. Rather than working together, European countries are striking bilateral deals with Russia. Many European state-owned or state-controlled energy companies have signed separate contracts with Gazprom: DONG (Denmark) in June 2006, ENI (Italy) in November 2006, and Gaz de France in December 2006.

While using the "divide and rule" method between EU members, Russia is also trying to play Europe against China. If Russia were to build new gas pipelines towards the east, China and Europe would end up competing for Russia's gas, which would put Moscow in a strong bargaining position. A Gazprom communiqué from April 2006 outlined this possibility in unveiled terms: "We want European countries to understand that we have other alternatives in terms of gas sales. We have a fast growing Chinese market." Russia tries to play the European

and Chinese markets against each other in order to maintain high prices for its natural gas supplies.

Russia is also trying to undermine the trans-European Energy Networks (the European Commission's alphabet-soup code for energy independence from Russia). The European-sponsored Nabucco pipeline, a project signed in July 2009 between Turkey, Romania, Bulgaria, Hungary and Austria, is meant to diversify the current natural gas suppliers and delivery routes for Europe and thus to reduce Europe's dependence on Russian energy. The project is backed by the European Union and by the United States. Gazprom is trying to undermine the Nabucco pipeline by building the South Stream pipeline, which will link Bulgaria to Austria, via Serbia and Hungary. Former German Foreign Minister Joschka Fischer was appointed senior advisor to the Nabucco project in 2009, thus competing with his former boss Gerhard Schröder (who heads the rival "Nord Stream" pipeline), whose pro-Russian policies he strongly criticized. As opposed to Schröder, Fischer is a vocal opponent of what he calls "Moscow's divide-and-conquer politics."

The fact that Gerhard Schröder and Joschka Fischer respectively head two competing natural gas projects is in itself an expression of two different visions for Europe's energy strategy. While the former communist countries of Central and Eastern Europe are eager to limit their dependence on Moscow, some Western European countries see in Europe's privileged ties with Russia both a geopolitical imperative and an economic boon.

1.2. The United States and China

In recent years, the United States has been competing with China over the planet's last oil reserves. China is the world's second largest energy consumer after the United States. China buys oil from countries that are antagonistic to the United States (such as Iran and Venezuela), as well as countries that has blacklisted by the United States for their human rights violations (such as Sudan). The United States and China are competing over Kazakhstan's oil (Kazakhstan has the Caspian Sea region's largest recoverable crude oil reserves). Kazakhstan exports oil and gas both to the West (via the Caspian Pipeline Consortium since 2003) and to China (via the Atasu-Dushanzi pipeline since 2006). Both the United States and China are trying to tap into the energy resources of the Caspian Sea basin. The United States championed the construction of the Baku-Tbilisi-Ceyhan (BTC) pipeline that delivers oil from the Caspian to the Mediterranean. The Chinese Government, for its part, is sponsoring the construction of a pipeline that would deliver Caspian oil directly to China. Tellingly, a representative of the US-China Economic and Security Review Commission (a Congress-chartered body) declared that "China's energy strategy in general is a concern for US energy security because of the Chinese government's interest in controlling oil and other natural resource production at the source, rather than making investments to ensure that there is greater supply on the world market."18

China's oil consumption increased from 1.7 million barrels a day in 1980 to 7.4 million barrels a day in 2006.¹⁹ In 1993, China ceased to be an oil exporter and became an oil importer. In 2003, China became the world's second largest oil importer after the United States. According to the International Energy Agency (IEA)'s 2009 World Energy Outlook Fact Sheet, China will

.

¹⁸ Klare, *Rising Powers*, p. 172.

¹⁹ Ibid., pp. 63-64.

overtake the US after 2025 to become the world's largest spender of oil and gas imports. The Chinese government has set up three large oil companies that are among the world's largest: China National Petroleum Corporation (CNPC), SINOPEC, and China National Offshore Oil Company (CNOOC). Since 2002, China's state-owned oil companies have been active in oil-exploration and production in Africa. CNPC is the world's leading oil production company in Sudan, and it is active in other African countries such as Nigeria, Algeria, and Chad. As explained by Mikkal Herberg, "For China's leaders, energy security is too important to be left to the markets, and so far its approach has been decidedly neo-mercantilist and competitive." In June 2005, for instance, CNOOC announced an \$18.5 billion bid to buy Unocal, an American energy firm with large oil and gas reserves in North American and in Asia (the bid was blocked by the US Congress).

The Chinese Government has been developing close ties with oil-exporting African countries, investing heavily in Africa and securing long-term concessions on African oil fields. As a result, China's economic clout in Africa is increasingly competing with America's. US oil firms are attracted to West Africa's offshore production sites. Tanker routes linking West Africa to the United States pass through the Atlantic Ocean (which is dominated by the US Navy) and avoid the congested choke points of the Straits of Hormuz and of the Bosporus.

China is the world's most influential and economically involved country in oil-rich Angola (in 2006, Angola became China's first oil supplier). The Sino-African summit held in Beijing in November 2006 (with 41 African heads of state) symbolized China's predominant role in Africa. Nearly one third of China's oil imports come from Africa (mostly from Sudan, Angola, DRC, and Nigeria). China has also become Sudan's main supplier of weapons, mostly to enable the Khartoum government to defeat the rebellion of Soudan's oil-rich south. The Khartoum government would not have been able to kill 200,000 people and displace 2.5 million in Darfur in the past five years without the diplomatic protection of China at the UN Security Council.

China's heavy investments in and cheap loans to Africa, make the IMF and the World Bank unattractive if not irrelevant in a continent where those two Washington-based institutions used to be the major finance providers. Indeed, African countries are more attracted by Chinese loans because China (as opposed to the IMF and the World Bank) does not demand institutional reforms involving economic and political liberalization.

China's energy policy is likely to eventually clash with the US military presence in East Asia. The Strait of Hormuz and the Strait of Malacca are altogether strategic energy waterways and sensitive geopolitical spots –both of them guarded by the US navy. The Strait of Hormuz is crossed both by Iranian oil tankers and by American submarines. The US Navy controls the sea routes in the Pacific and in the Indian Ocean, and thus the shipping and tanker routes that are vital to China's energy imports and exports. Over half of China's oil supplies transit via the Strait of Malacca, and one wonders how long China will accept America's dominant maritime role there.

US and Chinese energy interests are also clashing over Iran. China has been stalling US efforts to impose strong UN sanctions on Iran, mostly because such sanctions would affect China's

_

Klare, Rising Powers, p. 24.

economic interests.²² In October 2004, for instance, SINOPEC signed a \$100 billion deal with the National Iranian Oil Company (NIOC) to acquire a controlling stake in the Yadavaran oil field, whose production is expected to reach 300,000 barrels per day in the second decade of the twenty-first century.

2. Oil and the World Economy

The World's addiction to oil is a man-made tragedy. In 1912, Winston Churchill (then First Lord of the Admiralty) ordered the warships of the Royal Navy to switch from coal to oil. Churchill's purpose was to gain an advantage over Germany. Britain had both discovered large oil reserves in Persia and succeeded in sabotaging the German oil supply from Romania. During World War I, most armies followed the British example and switched to oil as well. Since then, oil has both been the cause of major conflicts and a tool to settle geopolitical rivalries.

During World War II, Germany attacked the Soviet Union partly to control the Caucasus oilfields. The Anglo-American sea blockade, by cutting off the German economy from vital oil imports, was critical in achieving victory. The Japanese government similarly invaded the Dutch East Indies in 1941 because of this territory's oil reserves. After the Yom Kippur War (1973), the Arab members of OPEC used the oil blackmail to build up an international momentum against Israel. Because of its dependency on Middle-Eastern oil, the United States backed the authoritarian regime of the Shah in Iran, and has been a strong ally of the Saudi theocracy for nearly eight decades.

US oil security is one of the reasons why America fought the first and second Gulf Wars (in 1991 and in 2003). Oil dependency also creates a heavy military burden for the United States. It is because of oil that America needs to protect the "oil states" (hence, as mentioned before, the 1991 Gulf War and the 2003 Iraq War), to guard the "oil routes" with the US Navy (The Straits of Hormuz, of Malacca, and of the Bosporus), and to fight radical Islam (Afghanistan, Pakistan). Until the withdrawal of American troops from Iraq in August 2010, US military forces consumed about 2 million gallons of fuel a day in Afghanistan and Iraq.²³

2.1. Oil and the "Resource Curse"

Oil exemplifies what economists call the "resource curse" or the "Dutch disease." As shown by the research of Paul Collier and Anke Hoeffler, countries that derive a significant percentage of their national income from natural resources are more likely to be engaged in civil war. ²⁵

²² The sanctions imposed by the UN in June 2010 are hardly "strong" ones. Even *The Economist*, itself a supporter of these sanctions, admitted that "searching ships and bouncing a few cheques is not about to get Iran to change its behavior, let alone to open its nuclear programme to inspection" ("A Step away from the bomb," *The Economist*, June 12th, 2010).

²³ "Greenery on the March," *The Economist*, 10th December 2009.

²⁴ The "Dutch disease" refers to the process of deindustrialization that can result from a sudden natural resource windfall. In the 1960s, the Netherlands discovered substantial deposits of natural gas. Thanks to the new income from natural gas export, the value of the Dutch currency rose, making manufactured exports uncompetitive and imports cheap. This phenomenon leads to the decline of the domestic industrial sector, a phenomenon also known as "deindustrialization."

²⁵ Paul Collier and Anke Hoeffler, "Greed and Grievance in Civil War," *Oxford Economic Papers* No. 56 (2004), pp. 563-595.

In many countries, oil deepens poverty, encourages conflicts and corruption, and stalls democracy. In his article "Does Oil Hinder Democracy?" Michael Ross argues that the absence of democracy in oil-exporting countries is the combined result of three factors: a. oil governments use patronage to prevent democratization; b. oil governments use their revenues to fund a repressive, police state; c. oil governments prevent economic diversification and thus the emergence of a middle class required for regime change and democracy. Oil revenues, for instance, enable the Islamic regime of Iran to remain in power despite the economy's poor performance and despite the lack of political freedom. It is because of its dependency on Saudi oil that the United States does not pressure Saudi Arabia to meet basic human rights standards.

Thomas Friedman has pointed out to the fact that "The price of oil and the pace of freedom always move in opposite directions in oil-rich petrolist states." Indeed, the only Arab oil-rich country that has held free elections and liberalized its political system is, incidentally, the first Arab state that is expected to run out of oil: Bahrain. According to Friedman, because of a "counter-wave of petro-authoritarianism, made possible by \$60-a-barrel oil ... regimes such as those in Iran, Nigeria, Russia, and Venezuela are retreating from what once seemed like an unstoppable process of democratization, with elected autocrats in each country using their sudden oil windfalls to ensconce themselves in power, buy up opponents and supporters, and extend their state's chokehold into the private sector." Oil creates "rentier economies" where the government buys political support with oil revenues instead of earning it through elections. Oil states create huge bureaucracies that employ docile citizens and deprive political opponents from economic opportunities. Gal Luft and Ann Korin note that "In authoritarian countries highly dependent on oil and gas for their income, such as Myanmar, Sudan, Azerbaijan, Uzbekistan, Kazakhstan, Angola, Nigeria, Chad and Russia, freedom has been in retreat since oil prices began their climb."

Nigeria is a good, and sad, example. Nigeria is Africa's most populous country (160 million people) and the world's eighth-largest oil exporter. It has earned about \$223 billion in revenues between 1999 and 2007, yet most Nigerians continue to be poor and Nigeria ranks 159th out of 177 on the UN's human-development index. Oil accounts for 90% of Nigeria's exports and 80% of the government's revenues. The country has failed to promote education, the rule of law, innovation and entrepreneurship. The economy is not diversified. In the public's psyche, wealth is not the product of innovation and hard work, but only a matter of getting closer to the oil tap. Despite billions of petrodollars flowing in since the 1970s, Nigerians are considerably worse off today than they were in 1980. About 70% of Nigerians live on the equivalent of less than \$1 a day, and a US intelligence report from 2005 speculated that Nigeria might be on its way of becoming a failed state.³¹

²⁶ Michael Ross, "Does Oil Hinder Democracy?" World Politics Vol. 53, No. 3 (2001), pp. 325-361.

²⁷ Thomas Friedman, "The First Law of Petropolitics." *Foreign Policy*, 25 April 2006. Friedman defines "petrolist" states as "states that are both dependent on oil production for the bulk of their exports or gross domestic product and have weak state institutions or outright authoritarian governments" such as Azerbaijan, Angola, Chad, Egypt, Equatorial Guinea, Iran, Kazakhstan, Nigeria, Russia, Saudi Arabia, Sudan, Uzbekistan, and Venezuela.

²⁸ Friedman, "The First Law of Petropolitics."

²⁹ Gal Luft & Anne Korin, *Turning Oil into Salt. Energy Dependence through Fuel Choice* (Booksurge, 2009), p. 20.

^{30 &}quot;Mission Impossible, Nearly," *The Economist*, 2nd August 2007.

³¹ "Hints of a New Chapter," *The Economist*, 12th November 2009.

With the exception of Malaysia's Petronas and Norway's Statoil, government-run oil companies are generally corrupt and inefficient. The citizens of oil-rich countries rarely benefit from oil revenues. Despite the hundreds of billions of dollars earned by Venezuela from oil, ordinary Venezuelans are poorer than they were 30 years ago. As Jeffrey Sachs and Andrew Warner demonstrate in their empirical study of 97 seven countries over a twenty-year period (1971-1989), countries that are rich in natural resources grow at a slower pace than countries that have no or little natural resources.³²

2.2. The Prospects of Oil Depletion

According to the International Energy Agency (IEA)'s Report World Energy Outlook 2005, "If governments stick with current policies ... the world's energy needs would be 50% higher in 2030 than today. Over 60% of that increase would be in the form of oil and natural gas." While the IEA report estimates that existing fossil fuel resources shall be able to meet global demand in 2030, it also points out to a growing (indeed, worrying) asymmetry between a small number of exporting countries and a large number of importing ones, as well as to increasing emissions of greenhouse gases due to continued fuel combustion.

Besides the growing feeling of "energy insecurity" and the environmental damages caused by fuel consumption, is the world about to exhaust its crude oil reserves? Since the early 1980s, worldwide oil extraction is higher than worldwide oil reserve discoveries. Between 1960 and 1989, the world discovered more than twice the amount of oil it produced. Between 1990 and 2006, worldwide oil discoveries were about half of oil production. As argued by Ferdinand Banks, "the aggregate amount of oil discovered is on a falling trend." About 365 billion barrels of oil were discovered in the 1960s, as opposed to 275 billion in the 1970s, 150 billion in the 1980s, and 40 billion in the 1990s. Nearly 80% of the world's global oil output comes from oil fields that were discovered over twenty-five years ago, and the output of these fields is declining. declining.

It might be argued that long periods of relatively low oil prices have discouraged oil exploration; yet the explorations and discoveries made when oil prices were high are not significant. Restricting the increase in global temperature to 2°C would require a decline in global demand for oil from today's 105 million barrels per day to 89 million barrels per day in 2030.³⁷

According to the IEA's chief economist, "the output of conventional oil will peak in 2020 if oil demand grows on a business-as-usual basis" and if no major oil reserve discoveries are made in the near future. This recent statement is significant, because it indicates that the IEA has joined the "pessimistic" side of the "peak oil" debate. In that debate, pessimists (such as the Association for the Study of Peak Oil and Gas, founded by Prof. Kjell Aleklett from the University of Uppsala, Sweden) argue that global oil supply has peaked or is about to peak and that, given consistent projections of increasing worldwide demand, the world economy is

³⁸ Ibid.

heading toward disaster. In his book *Twilight in the Desert*, oil expert Matthew Simmons argues that production from Saudi Arabia (especially from Ghawar, the world's largest oil field) has reached a peak.³⁹ Other leading "petro-pessimists" are Colin Campbell and Jean Laherrère, who predicted in 1998 that the oil peak would happen in 2007.⁴⁰

Optimists (such as Cambridge Energy Research Associates, an energy research firm based in Boston), on the other hand, believe that higher oil prices will enable oil firms to afford the exploration of new oil fields, as well as new technologies that will increase the amount of oil extracted from existing fields. The Island of Sakhalin, for example, could provide new oil resources. Russia, together with international energy companies, is actively exploring oil and gas resources there. However, even though an estimated 45 billion barrels of oil equivalent lie beneath the icy seas off the shores of Sakhalin, developing those resources is proving both challenging and costly.⁴¹

The fact that the IEA is pessimistic about future oil supplies seems to be the result of a study the agency conducted recently. It analyzed the production trends of 800 oil fields in 2008, and concluded that the decline in annual output from many of these fields could average 8.6% in 2030.⁴² In such a context, even if oil demand were to remain flat (an unlikely scenario), the world would need to find over 40 million barrels per day of gross capacity only to offset the decline predicted by the IEA.

Today, oil is a depleting asset. Oil companies lose assets if they don't invest to increase their production capacities and to find new fields. According to the IEA, "converting the world's resources into available supplies will require massive investments ... Meeting projected demand will entail cumulative investment of some \$16 trillion from 2003 to 2030, or \$568 billion per year." Most of that money will go not to increase global supply, but merely to replace output from today's ageing oil fields. In other words, large oil companies (and oil exporting countries) are threatened by a rundown of reserves.

According to Matthew Simmons, the "Peak oil debate" boils down to an argument about timing. Optimists believe that technology will advance quickly enough to offset declining production from large oil fields. Pessimists, by contrast, think the decline will come too soon and that it will be too sharp for the world economy to adapt in time.

If and when the oil peak does occur, one immediate consequence will be a sharp increase in oil prices (since demand will exceed supply). Most countries will not be able to afford oil, and they will experience what Sascha Müller-Kraenner calls "energy poverty." Yet even reach countries are starting to show concern about their reliance on oil: they, too, would be badly affected by the economic consequences on an "oil peak," and they no longer wish to be held hostages by unfriendly, or even hostile, regimes.

Regardless of the real prospects of oil depletion, the oil age might end long before the world runs out of oil. After all, the Stone Age did not end for lack of stone.

3. Weaning the World from Oil

Former US President George W. Bush called upon America, in his 2006 State of the Union speech, to wean itself from oil. He declared that "our addiction to oil must end" and called for reducing US oil imports from the Middle East by 75% by 2025. During his presidential election campaign, Barack Obama released the "New Energy for America Plan" (NEAP), which called among other things for eliminating US oil imports from Venezuela and the Middle East within ten years. In his first address as President, Obama declared that "America's dependence on oil is one of the most serious threats that our nation has faced. It bankrolls dictators, pays for nuclear proliferation, and funds both sides of our struggle against terrorism. It puts the American people at the mercy of shifting gas prices, stifles innovation and sets back our ability to compete." President Obama's plan for America is that 10% of electricity be generated from renewable sources (e.g. wind, solar, hydroelectric, and solar) by 2012 and 25% by 2025.

The United States will not be able to achieve energy independence without weaning itself from oil, for a simple reason: It consumes a quarter of the world's oil but owns less than 3% of the world's proven reserves. The United States is more dependent on oil imports today than it was forty years ago because of a declining domestic production. In 1973, the US imported 35% of its oil consumption, as opposed to 60% in 2007. Among the United States' main oil providers are Saudi Arabia and Venezuela.

The United States' dependence on oil is not related to power generation. Indeed, between 1 and 2% of the electricity used in the United States is produced from oil (see chart: "Sources of Power Production in the US"). Similarly, only 4% of the EU's electricity is produced from oil. Since the industrialized economies no longer generate electricity from oil, promoting nuclear power or renewable energy will have no effect on reducing dependency on oil. Building more nuclear plants, solar panels and wind farms would only reduce the use of coal and gas in power production. This would have a positive impact on the environment (because producing electricity from coal is polluting), but nearly no impact on oil consumption. The United States is nearly self-reliant for power generation, but it is entirely dependent on imported oil for transportation.

3.1. The Source of Oil Dependency

Oil dependency is related to transportation because oil enjoys a worldwide monopoly over fuel for transportation. The United States (like most developed economies) depends on oil for transportation (by land, sea, and air). While oil was an all-purpose fuel in the US economy until the energy crisis of the 1970s, today it is mostly a transportation fuel. About 70% of the oil consumed in the United States is used to produce fuel for cars, trucks, ships and airplanes. Thus,

⁴⁸ Shaffer, *Energy Politics*, p. 130.

the only way to really reduce oil dependency in a country like the United States is to change the energy consumption of engines.⁴⁹ In other words, the world will be able to wean itself from oil only by breaking the monopoly of oil in transportation. The same way that Churchill's decision to switch from coal to oil generated our dependency on oil, switching from oil to other combustibles is key for achieving "freedom from oil." As argued by Gal Luft and Anne Korin, there are precedents to the world's overdependence on strategic commodities. Salt was once such a strategic commodity. Because salt used to have a monopoly over food preservation, it was a strategic commodity over which wars were fought. Salt, however, lost its monopolistic status with the advent of canning, of electricity, and of refrigeration.⁵⁰

Paradoxically, one major obstacle to the gradual replacement of oil is the fact that oil prices do not reach unsustainable levels. Oil is not a freely traded commodity. Its price is controlled by the OPEC cartel. Thanks to its dominant position within OPEC, Saudi Arabia maintains oil prices at affordable levels so as to discourage the search for oil substitutes, which are generally costly. It is no coincidence if Saudi Arabia is showing signs of concern about the growing awareness, in the West, of the dangers of oil dependency. Prince Turki al-Faisal, Chairman of the King Faisal Centre for Research and Islamic Studies and a former Saudi intelligence and ambassador to the US, recently wrote that "this 'energy independence' motto is political posturing at its worst -- a concept that is unrealistic, misguided, and ultimately harmful to energy-producing and -consuming countries alike."

3.2. Ending Oil's Monopoly over Transportation

In January 2008, Renault-Nissan and Better Place signed a partnership agreement to launch a new electric car project. Renault-Nissan is building the electric vehicles while Better Place is building the electric recharge grid. Better Place's model provides a solution to the time required to charge a battery and to the shorter driving range of electric cars compared to gasoline cars. Better Place's electric recharge grid will enable its customers to recharge their cars wherever they park. More significantly, battery switching stations will enable to switch the car's battery in less time than what it takes to fill a tank with gasoline. Those switching stations will be spreadout just like gas stations, and switching batteries will not involve any extra cost for the customer since the battery is owned by the company and since the customer is only charged per kilometer.

Electric cars will dramatically decrease the world's addiction to oil, but their contribution to the global reduction of carbon dioxide emissions will be enhanced if the electricity they use is produced from renewable sources. This electricity can also be produced from coal, but doing so would limit the positive impact of electric cars on the environment –though it would not impede the electric car's contribution to the decline in oil consumption.

Replacing gasoline cars with electric car would only partially reduce the world's dependency on oil because of the massive use of petroleum by ships airplanes (both civil and military). There might, however, be promising scientific breakthroughs in that area as well.

According to *The Economist*, "diesel ... is the aviation fuel of the future." Many of the light planes manufactured in Europe now use diesel, both for cost and air-quality reasons. Aviation fuel could therefore use biofuels, such as the type recently developed by Purdue University and favorably rated by the US Federal Aviation Administration (FAA). The US Air Force is introducing the use of synthetic fuels made from gas derived from coal or biomass. Its target is to use a 50:50 blend of synthetic and traditional jet fuel for half of its aviation requirements by 2016. As for the US navy, it is testing biofuels in ship turbines. It also recently launched an amphibious assault ship that runs on an electric motor at low speed. The Navy's ambition is to ultimately develop all-electric ships. In the United States, the State of Arizona recently set-up a \$100 Million project together with the National Energy Technology Laboratory (NETL) to produce airplane biofuel from algae.

Biofuels, of course, are also used in cars. Brazil is the first country that ended oil's monopoly on in its transportation through biofuels. Three decades ago, Brazil imported about 80% of its oil supply. After the 1973 Arab oil embargo, Brazil both started drilling oil off its shores and investing into a sugar-based ethanol industry. Because of its warm temperatures and long rainy seasons, Brazil has the ideal climate for sugarcane production. Today, 80% of the new cars sold in Brazil are "flexible fuel" vehicles, which means that they run on a combination of gasoline and ethanol. When oil prices soared in 2008, ethanol became Brazil's primary transportation fuel.

There are two main types of crop-based biofuels: ethanol and biodiesel. Ethanol is an alcohol produced from sugar cane, maize, or wheat. It is used as an additive in gasoline (generally 10%) to reduce carbon emissions and improve engine performance. Ethanol is the most widely used biofuel in the United States, where it is almost entirely made out of corn. Biodiesel, on the other hand, is derived from natural oils such as palm oil or soybeans oil, and is used for diesel engines (Rudolf Diesel had originally designed his engine to run on peanut oil). The European Commission's Renewable Energy Directive (RED) requires 10% of fuels in the EU to be composed of biofuels by 2020.

The assertion that growing crops for ethanol production is taking away food from hungry people is a popular (if not populist) claim but not necessarily a sound one. According to a study by the US Departments of Energy and Agriculture, 1.3 billion tons of plant matter could be collected from America's soil without affecting food production. Converting this plant matter into ethanol

⁵⁵ Ibid.

⁵⁶ Biofuels are generally divided between first-generation biofuels (i.e. crop-based biofuels) and second-generation biofuels (i.e. fuels derived from waste, algae, or other non-food vegetation).

would add up to the equivalent of 350 billion liters of oil, i.e. 65% of the current oil consumption in the United States.⁵⁷

In addition, there are millions of unused hectares of fertile lands in sub-Saharan Africa and in South America. Setting-up large agricultural projects for ethanol or biodiesel production does not take away food from anyone since that food in not being produced in the first place. Setting-up large sugar-cane plantations for ethanol or large palm tree plantations for biodiesel can provide work for millions of otherwise unemployed or underemployed farmers. Moreover, not all of the crop production needs to be used for ethanol; part of it can be used for feeding the local population based on ad hoc agreements between investors and governments. Finally, crops can be combined so as to meet the food needs of local populations (for instance, combining sugar cane plantations for ethanol with maize plantations for local consumption). Surely, many sub-Saharan African countries that suffer from food shortages because of poor productivity would benefit from foreign investments in large agricultural projects that combine biofuel production with local food supply.

Biofuels do not need to be produced from crops. "Second generation" biofuels are produced from waste, algae, and non-food vegetation. One example is cellulosic ethanol. Cellulose is a major component of grasses, wood, and agricultural residues (such as corn stalks). It can be broken down into sugars, which in turn can be used for ethanol production. Producing ethanol from cellulose is more expansive than producing ethanol from crops, but costs are declining. Another example is algae. Algae double their mass in a few hours and produce thirty times as much oil per acre as sunflowers. Most significantly, algae devour carbon dioxide, the primary culprit in global warming. Growing algae like a crop enables the production of biofuel. Biofuels will likely become more efficient and less controversial if cellulose-based (or second generation) biofuels progressively replace plant-based (or first generation) biofuels.

For all their advantages and disadvantages, however, biofuels alone will not be able to end the monopoly of oil over transportation. In order to stall the expansion of alternative fuels, OPEC manipulates oil supplies to lower the price of oil whenever importing countries are making headways toward alternatives. This is why investments in biofuels remain economically risky. Only the use of electricity as a transportation fuel can break the monopoly of oil. Fueling a car on electricity costs about two cents a mile. Oil prices would have to drop to less than ten dollars a barrel for gasoline to be as cheap. OPEC would unlikely be able to increase supply sufficiently in order to drop oil prices to less than ten dollars a barrel. To avoid the risky dependency on exclusively electric cars (an electric blackout caused by natural disasters could cripple transportation for entire regions), plug-in hybrid electric vehicles (PHEV), which run on electricity and automatically keep running on liquid fuel (including biofuel) when the electrical charge is used up, are most likely to become the most widespread vehicles in the future.

Conclusion

Achieving energy security is a strategic imperative because energy competition is a major cause of geopolitical tensions. Those tensions are likely to deteriorate with the combined rise of growing energy consumers (such as China and India) and of the depletion of oil reserves.

⁵⁷ "Grow Your Own," *The Economist*, 19th July 2008.

Reducing oil consumption is key to improving energy security, and it can only be achieved by ending oil's monopoly over transportation through the combined spread of biofuels and of electric cars. While the diversification of energy production (essentially with nuclear energy and renewable energies) will contribute to the reduction of carbon emissions, its impact on oil consumption will be marginal at least in the US and in the EU since those developed economies barely use oil to produce electricity.

The transition from oil monopoly to the widespread use of vehicles using electricity and biofuels will transform the global energy balance of power. Oil-producing countries will lose some of their geopolitical clout. By contrast, countries and regions that lack the economic power of OPEC have the potential of becoming major players in the global energy market. African and South American countries that are rich in lithium (a metal essential to the production of batteries used in electric cars) and that produce or can produce large amounts of sugar cane (used for ethanol production) will acquire an international stature they lack today.

The knowledge and technologies required to end the monopoly of oil over transportation are available and are being improved. Political will is what will determine the ability of scientific knowledge to free the international economy from the destabilizing grip of oil. While oil-importing countries and oil-exporting countries obviously have diverging interests in that regard, free nations whose fossil energy resources are scarce have an interest in working together toward energy independence, not only for their own sake but for the sake of international security.
